

Background

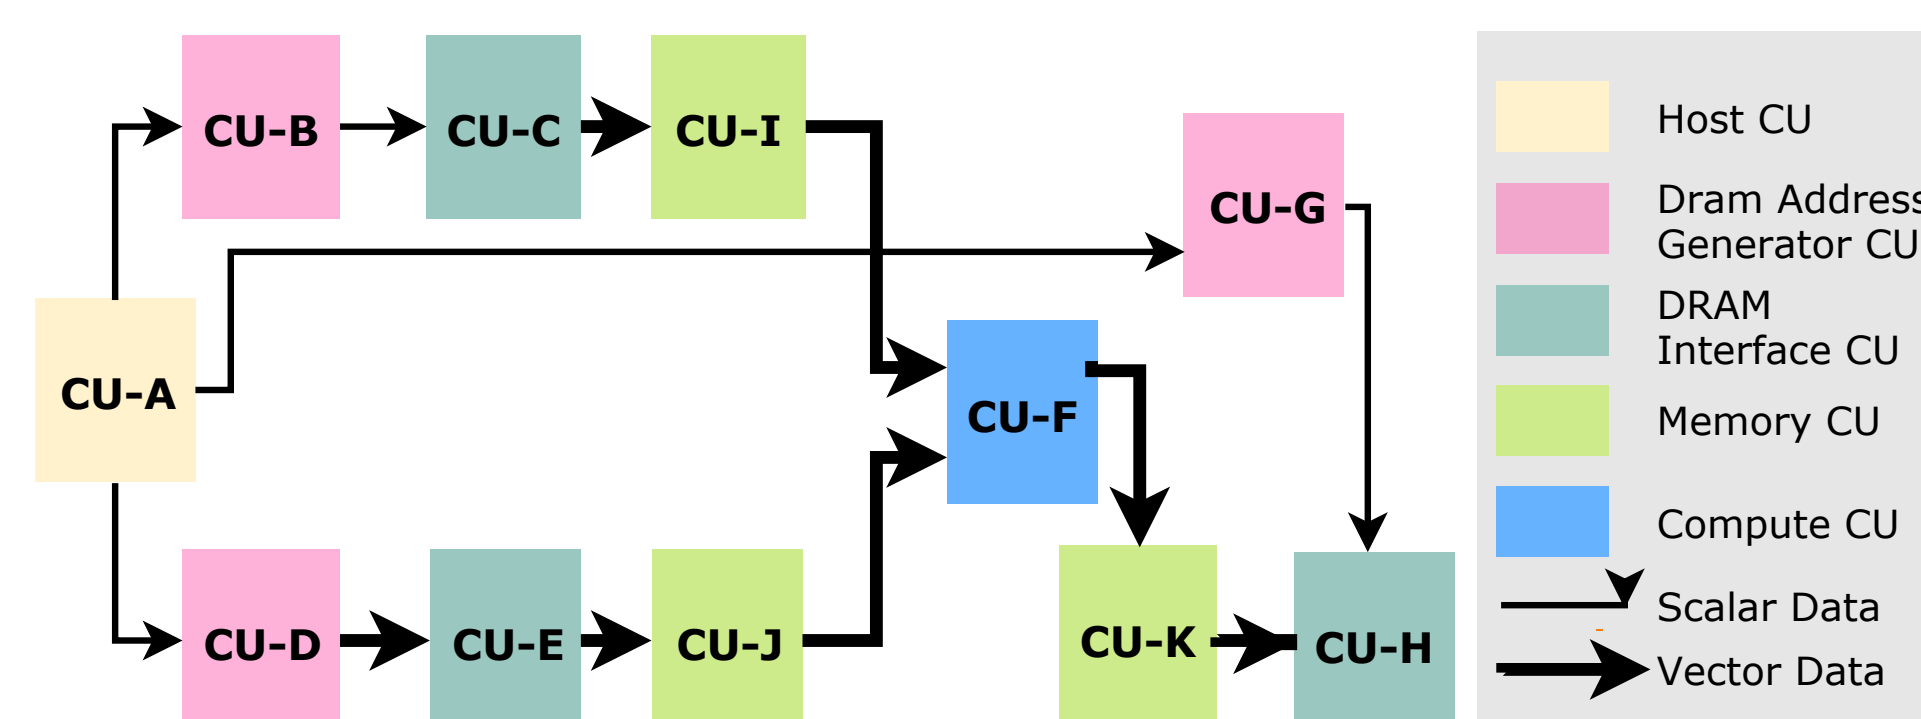

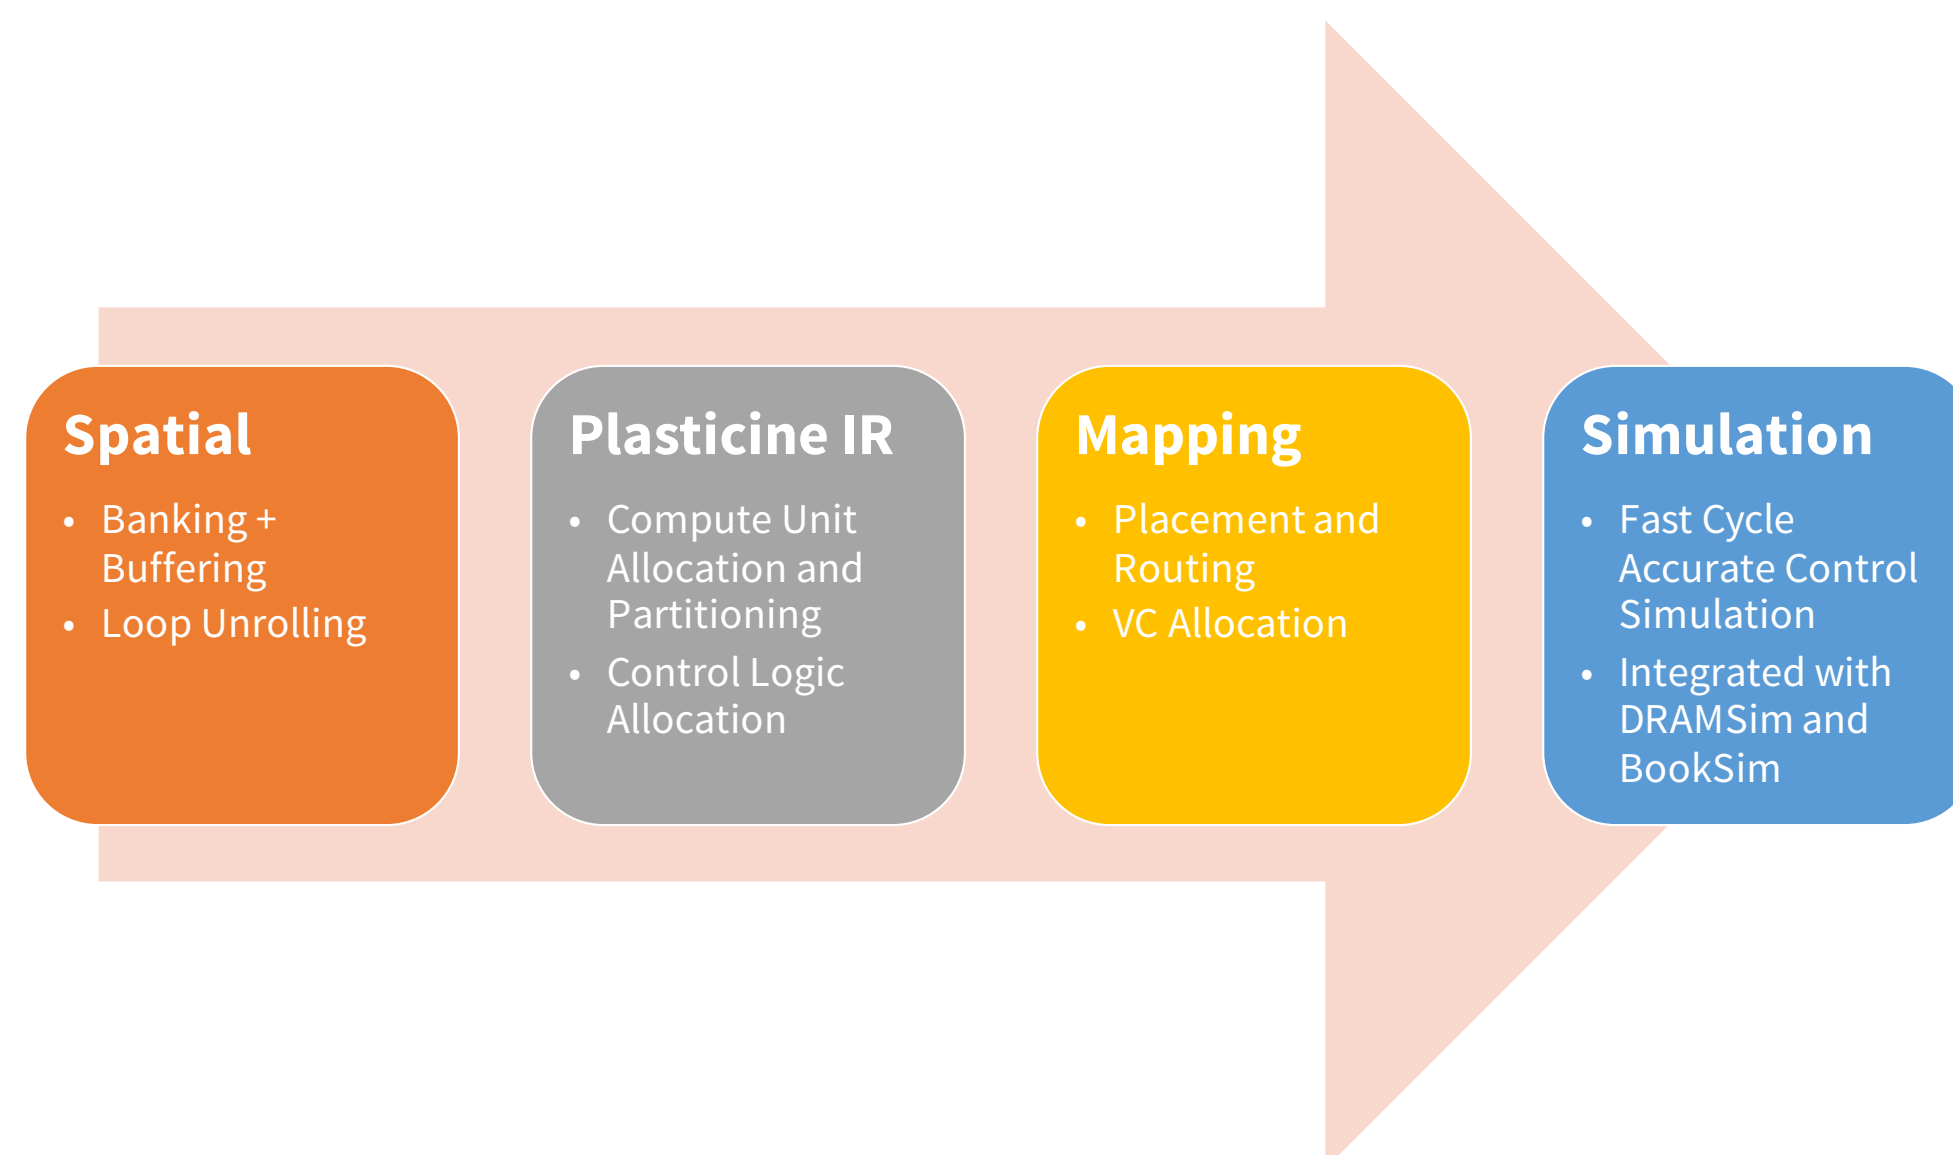

Plasticine is a vector Coarse-Grained Reconfigurable Array:

- 6-stage, 16-lane 32-bit floating point SIMD pipelines
- Distributed 256-kByte memories
- Memory controllers support dense and sparse DRAM access

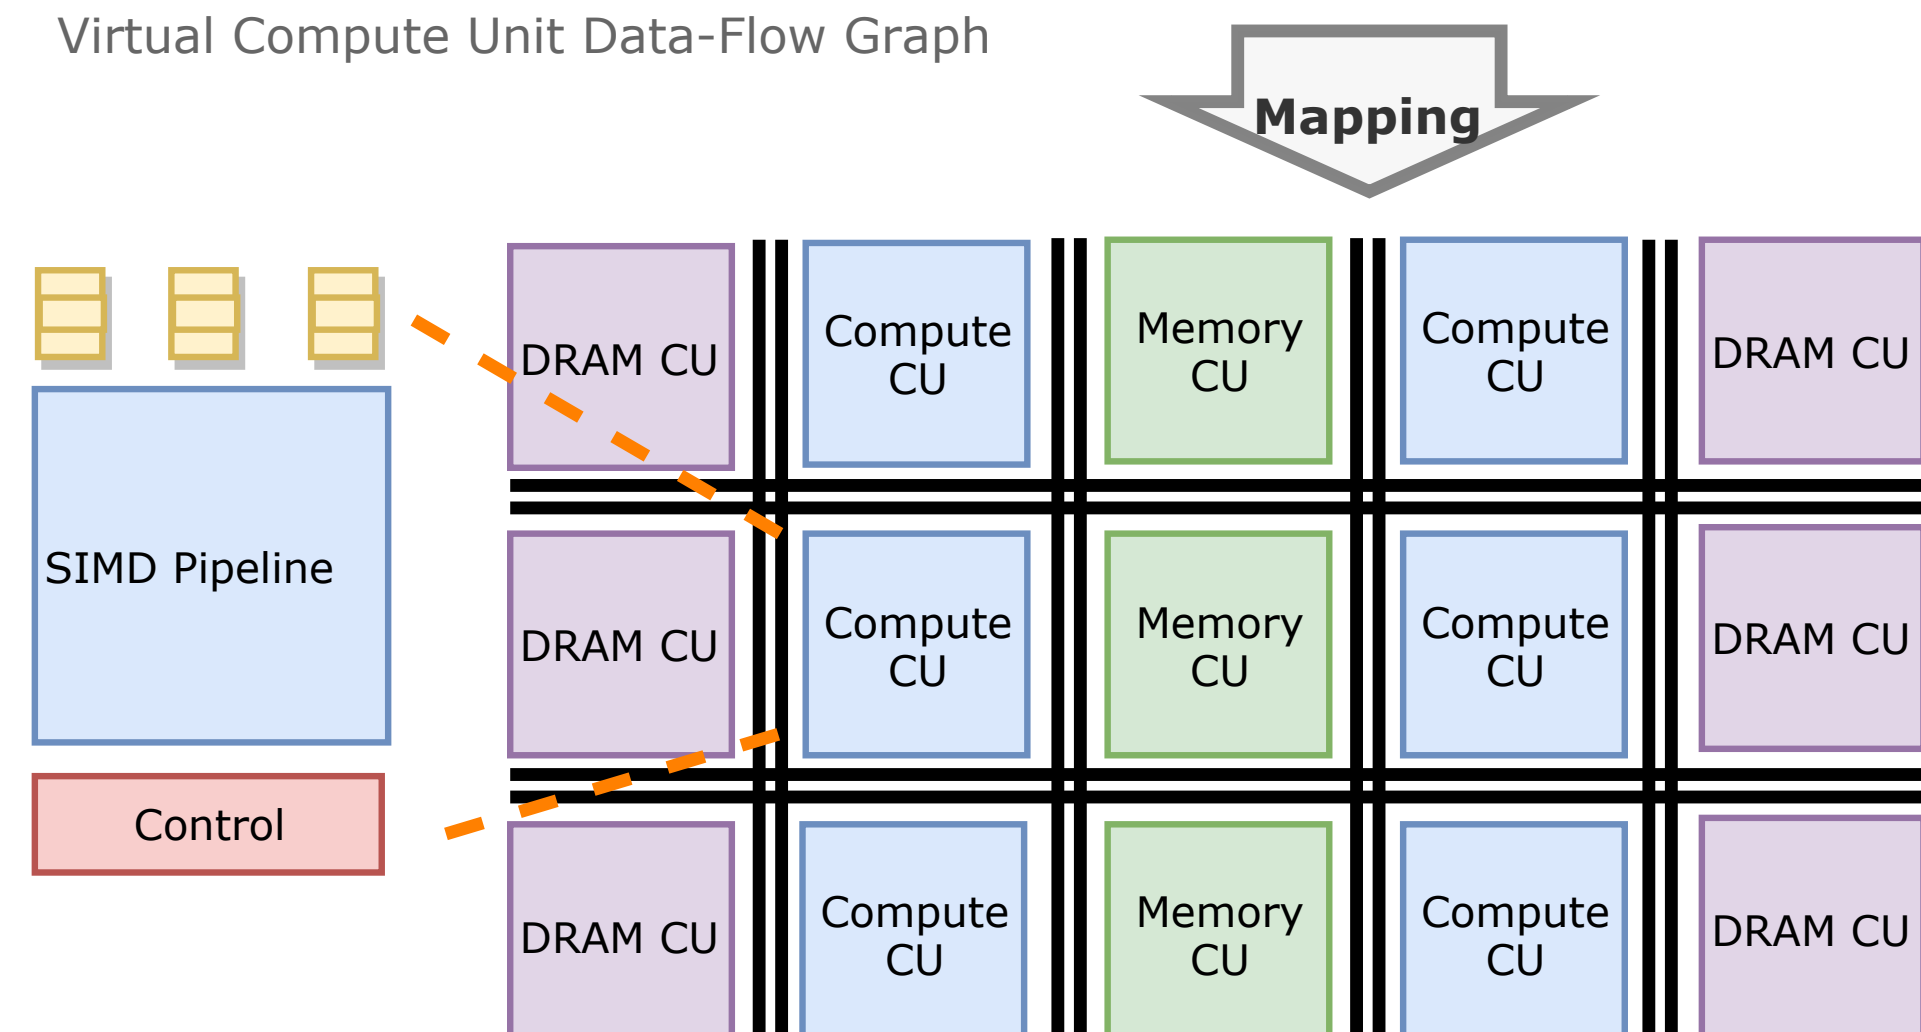

Plasticine demonstrated up to 95x speedup and 77x performance per Watt vs. a Stratix V FPGA.

How can we retain Plasticine's performance and efficiency while enabling new applications?

Compiler & Mapping Flow

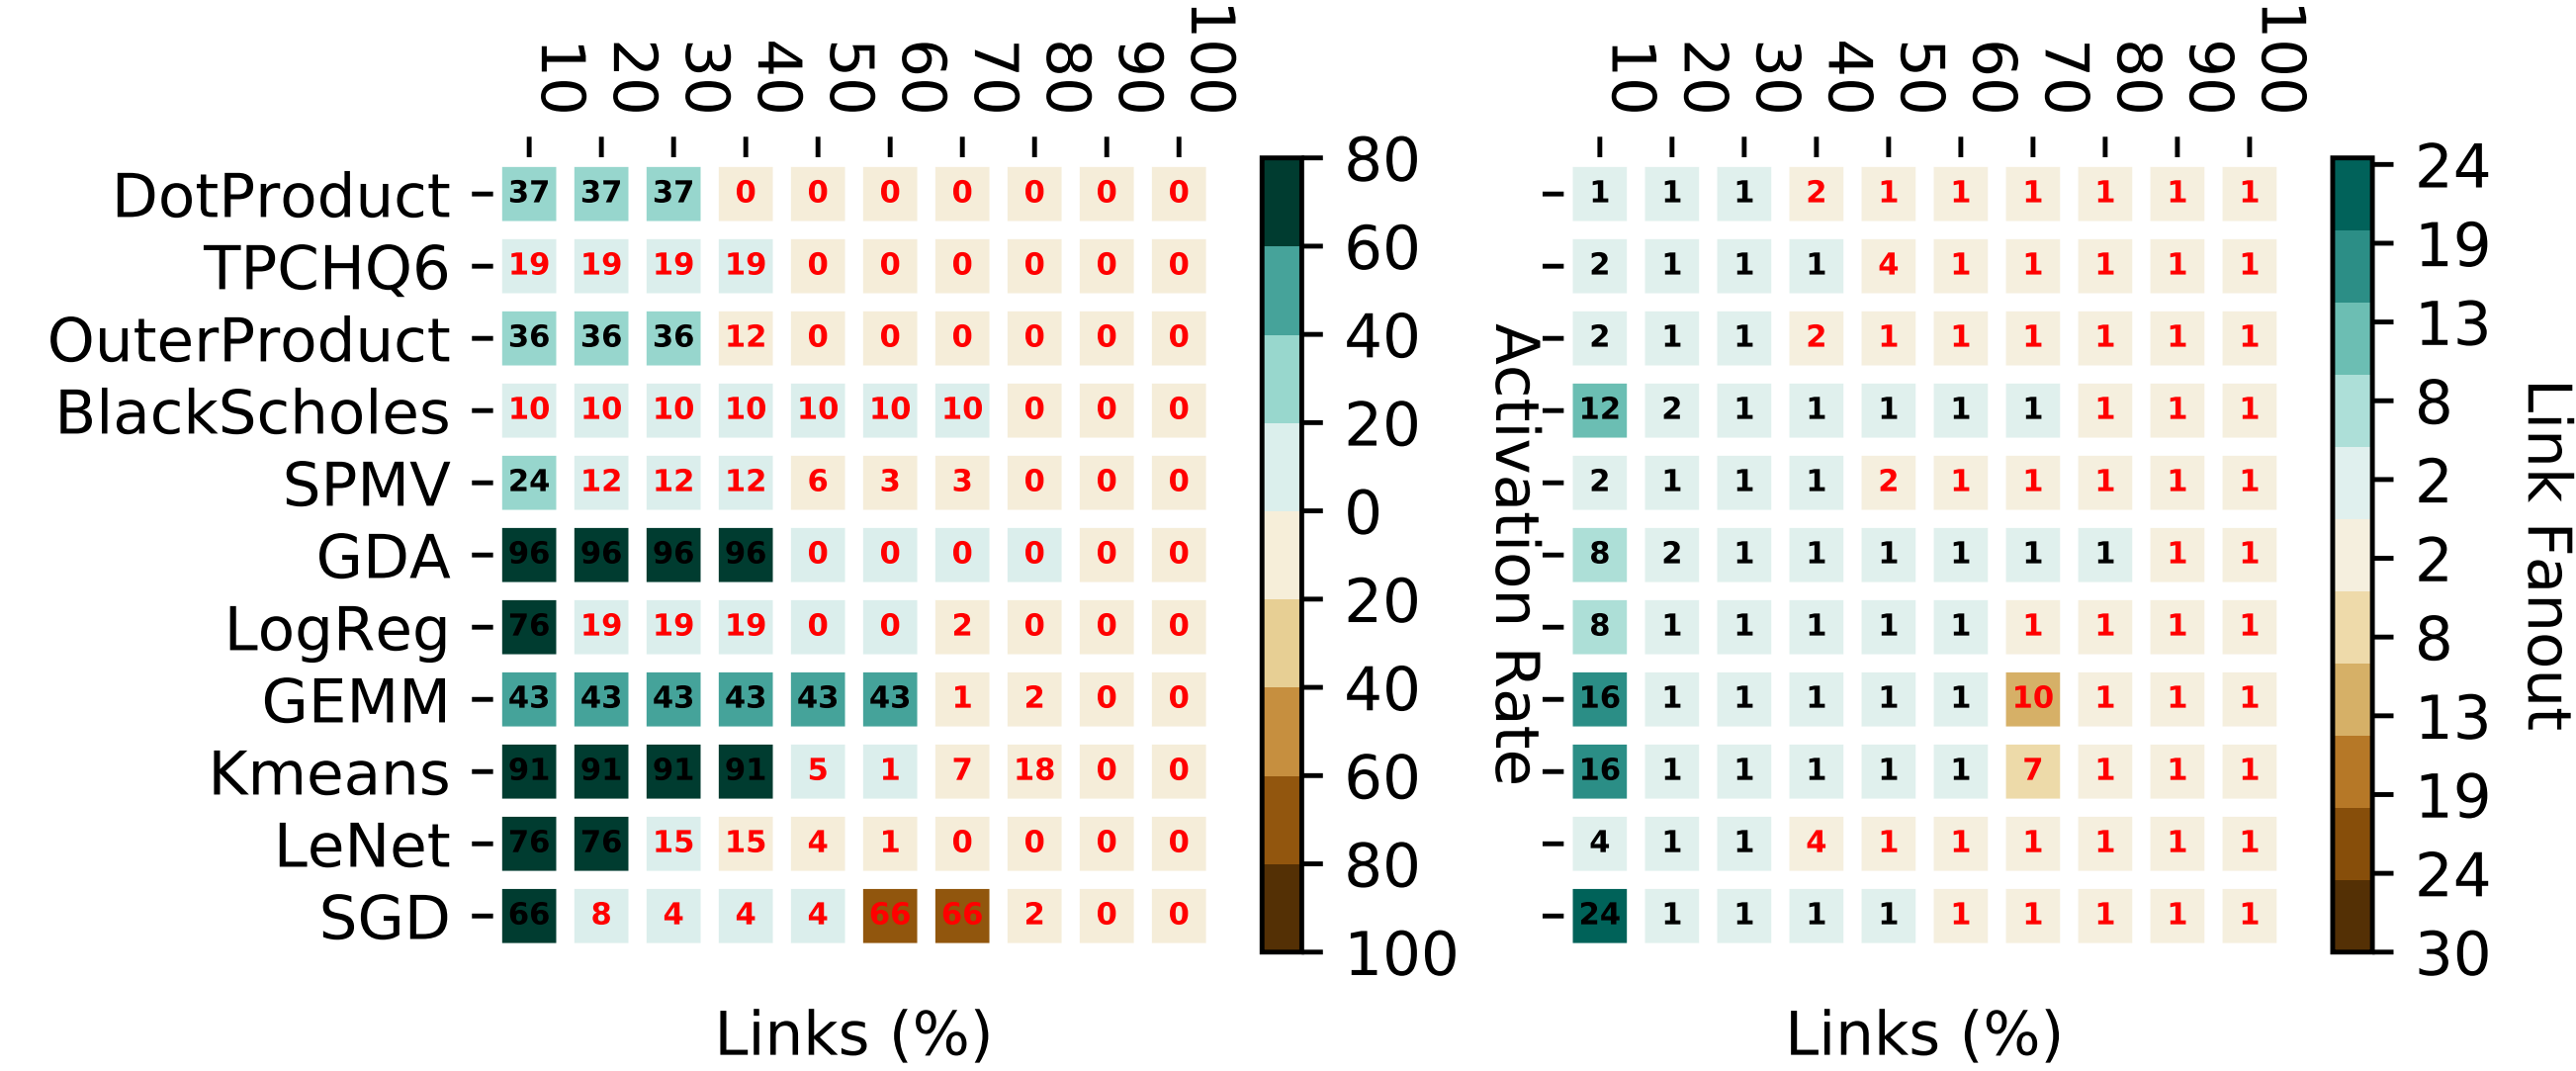

Virtual Compute Unit Data-Flow Graph

Physical Compute Unit

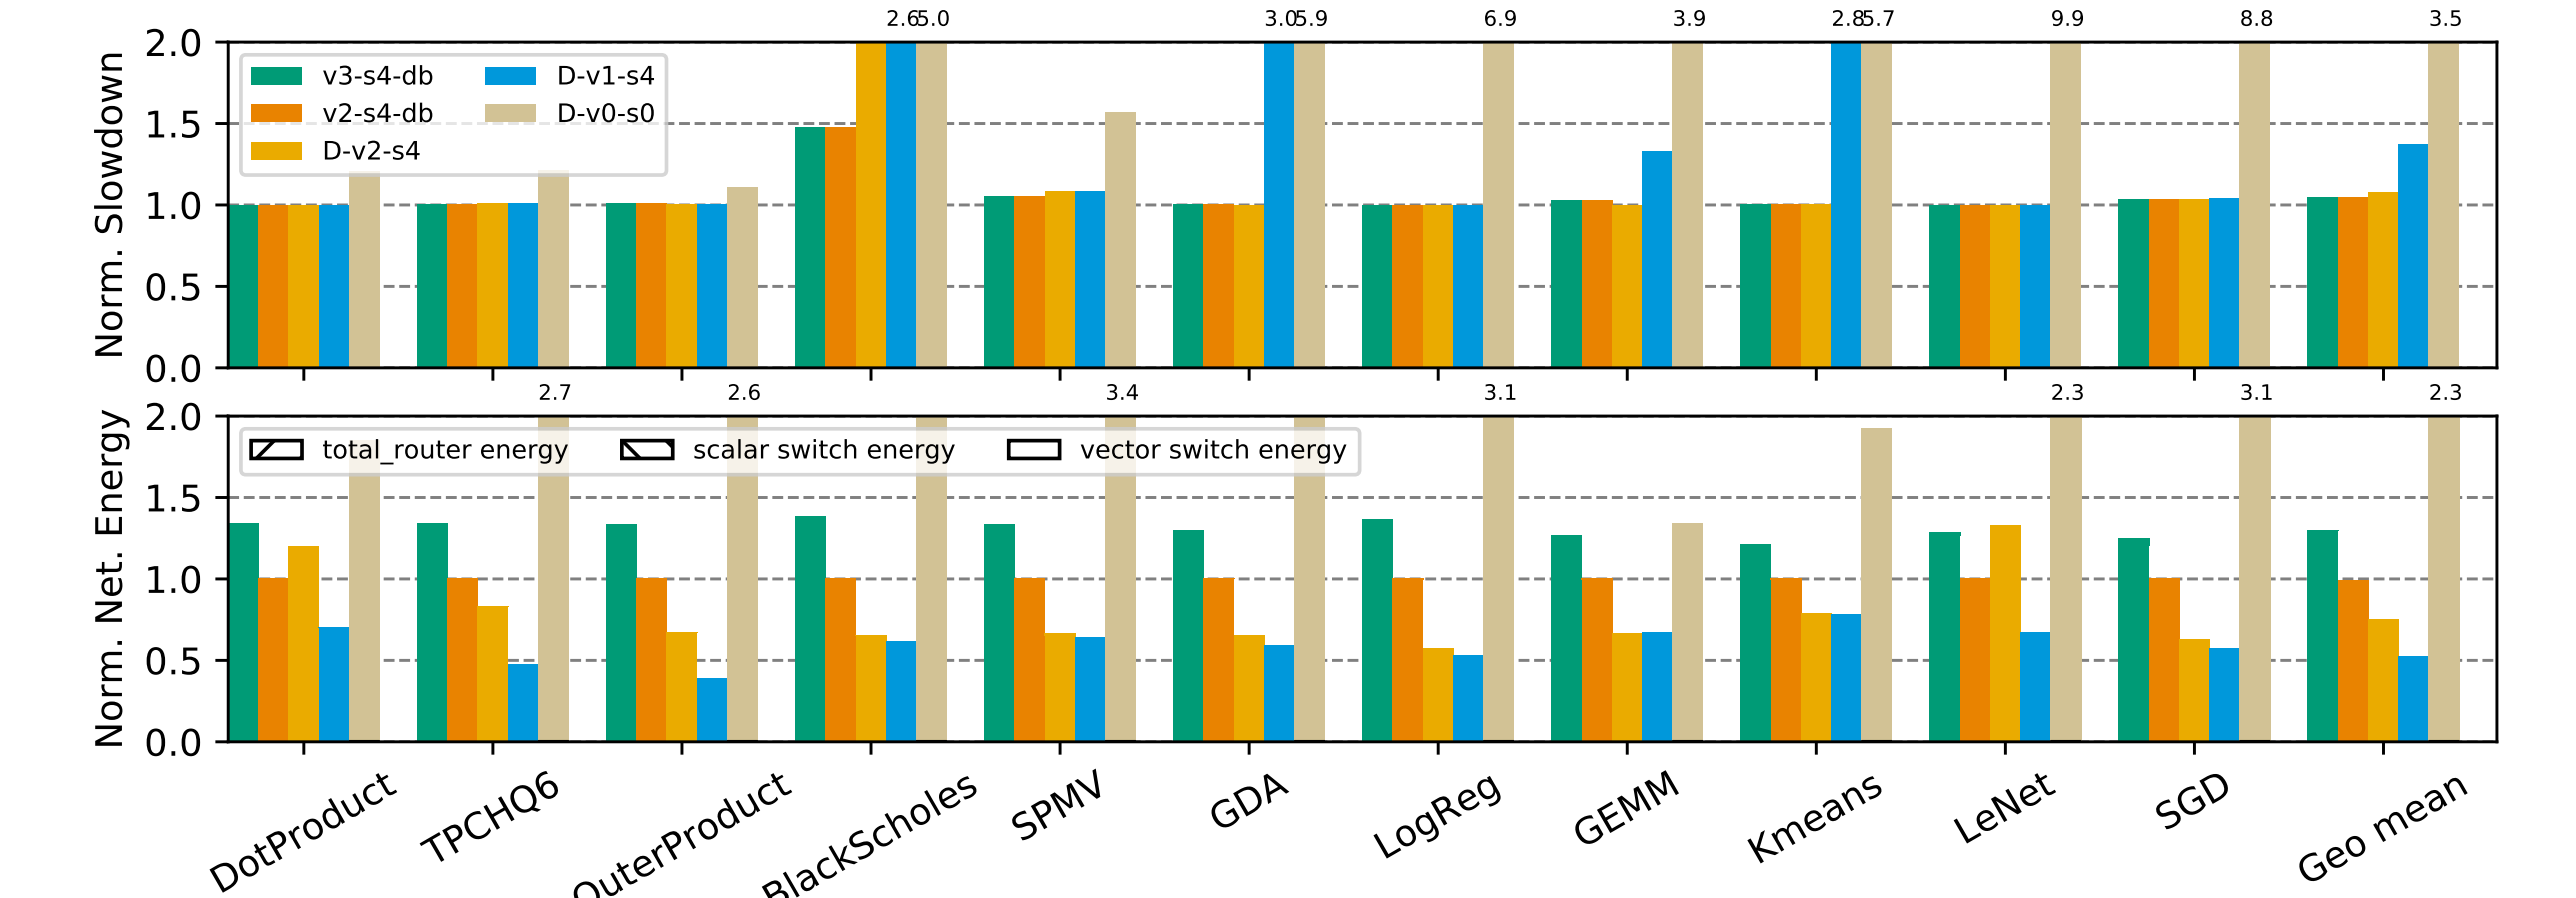

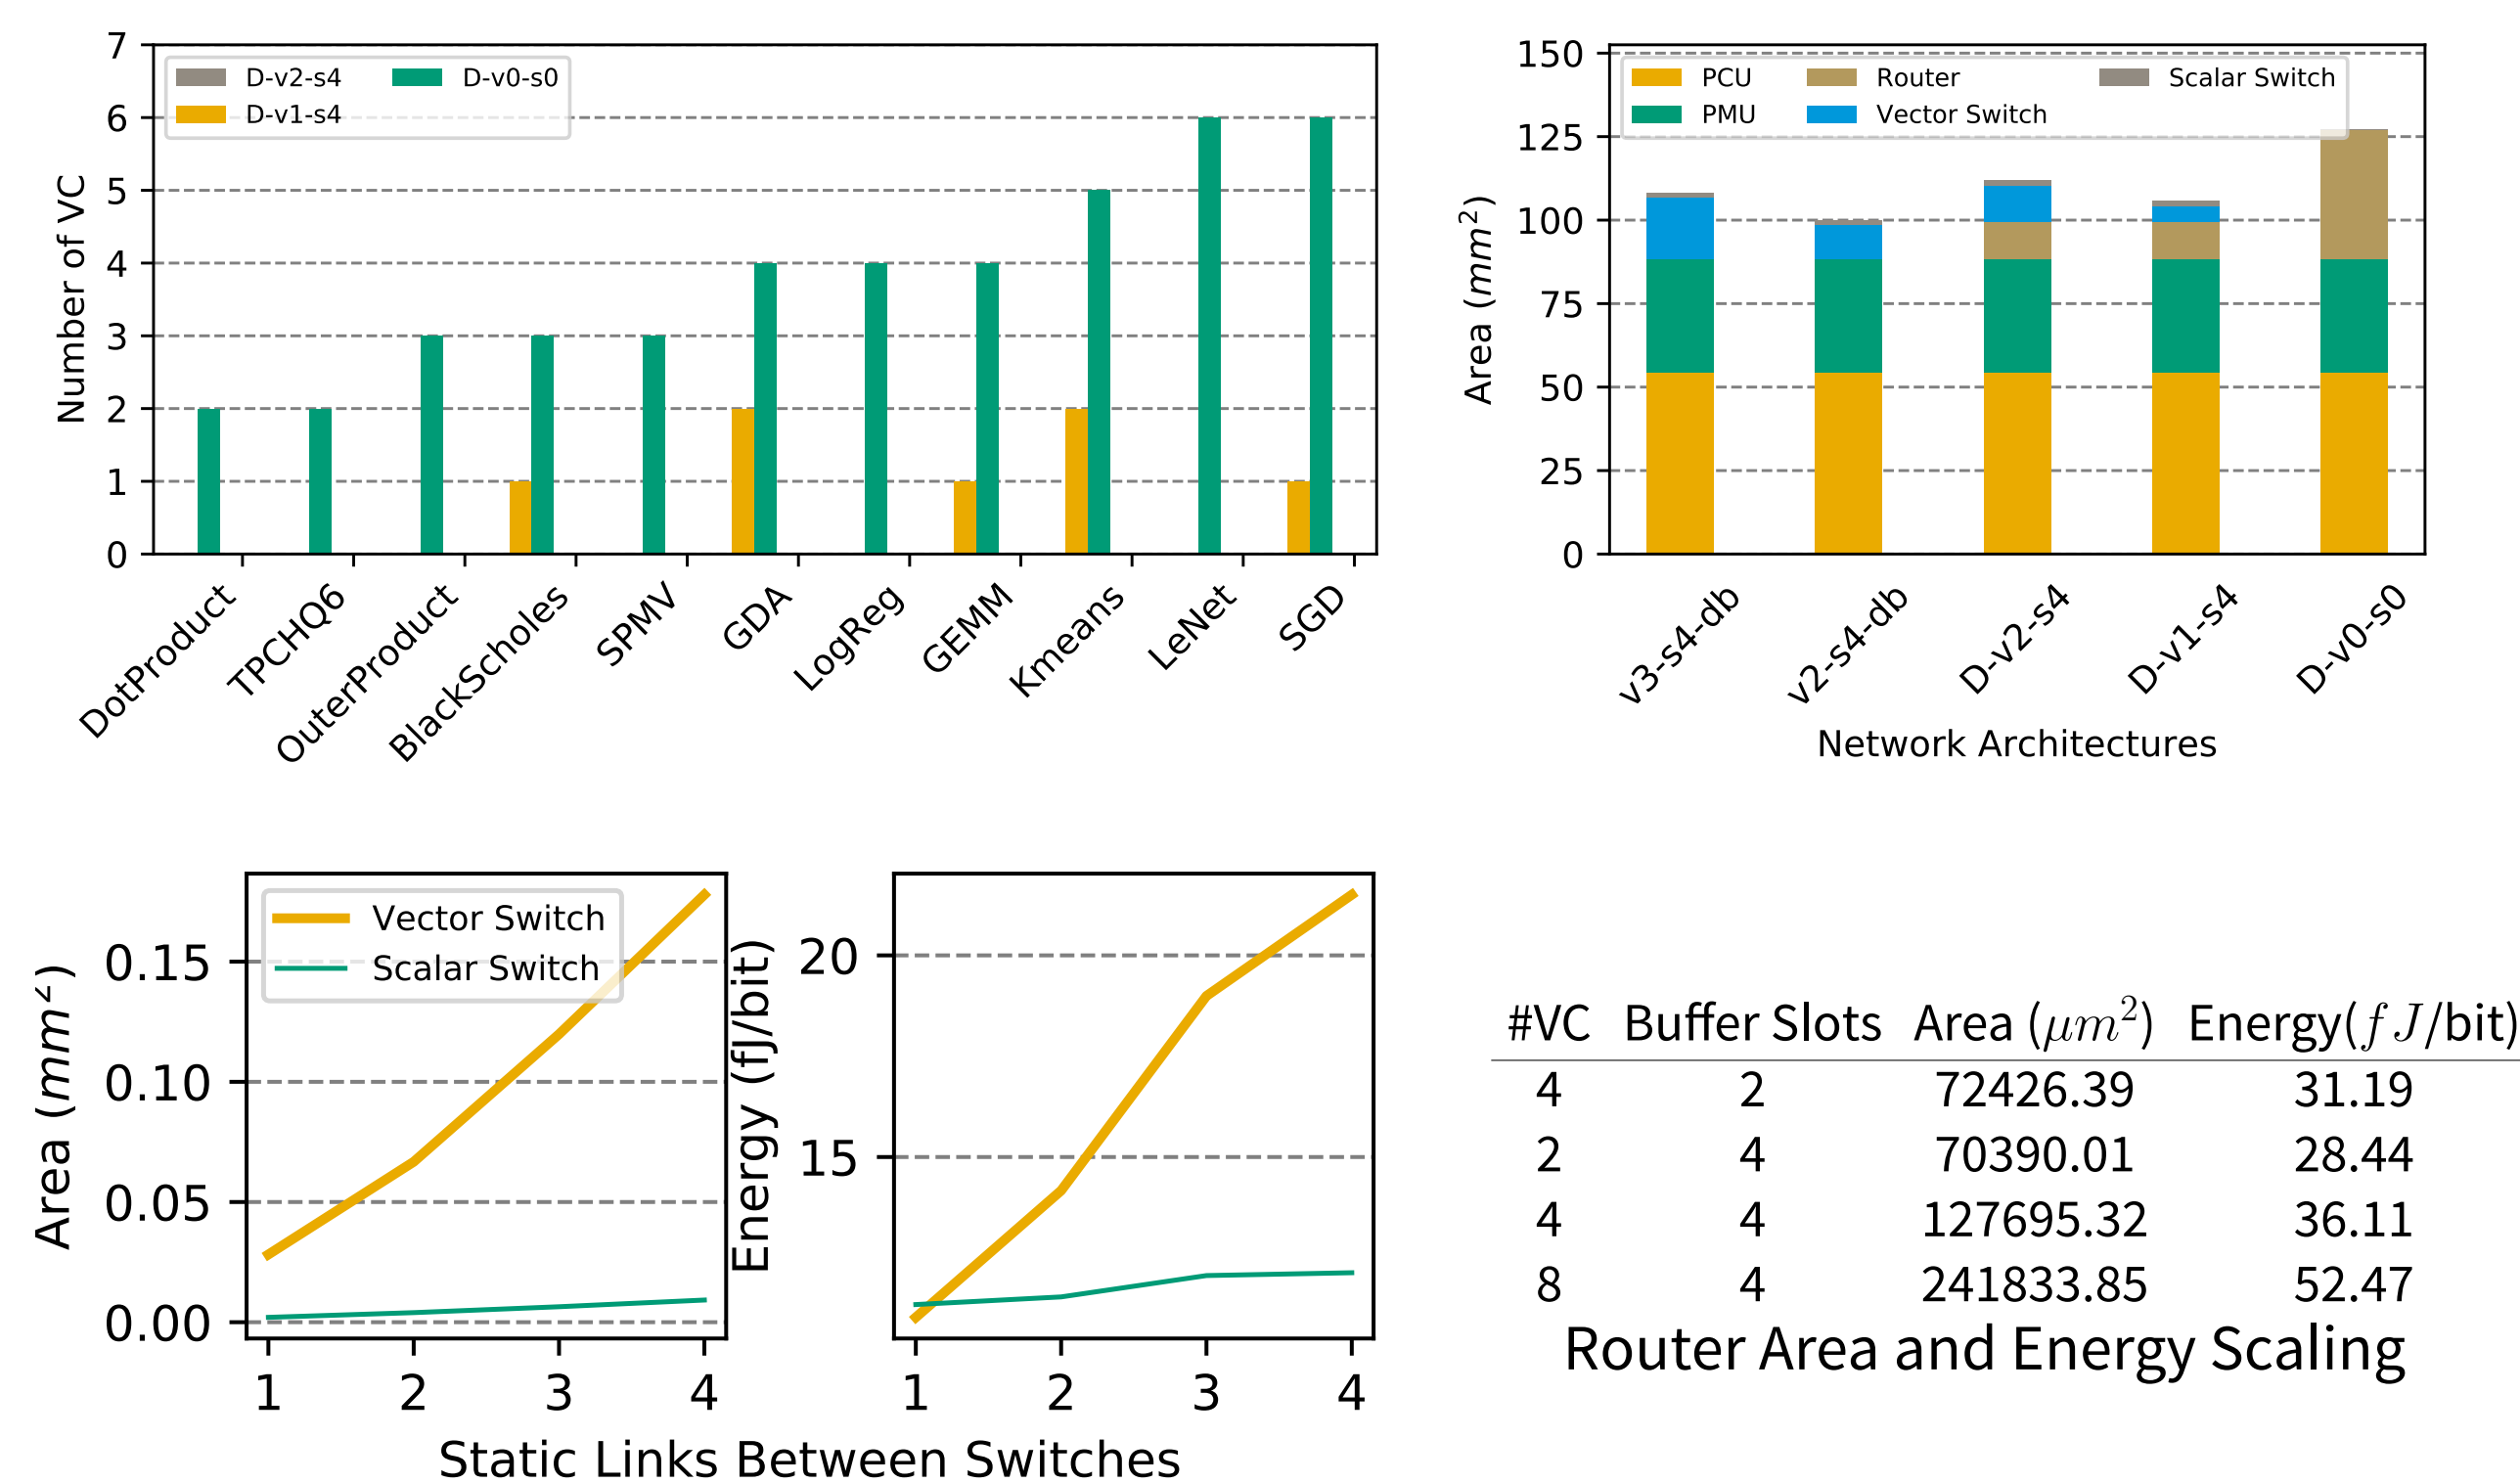

Hybrid Networks

Different applications have different link activation rates and fanouts:

How can we improve link utilization?

- Use static network for high-bandwidth and broadcast links
- Use dynamic network to encourage link sharing on low-activation links
- Specialize networks at different granularities

Future Work

Minor hardware additions to the PCU allow fast sort:

Multi-way merge reduces memory traffic:

What's the next class of applications to target?

- Transactional/online applications?
- Streaming data analytics and networking?
- Graph analytics?

What advances will be necessary to target these applications?

Improve achieved compute density for more generic control constructs

- Data-dependent conditionals
- Finite state machine-based control
- Parsing support

Support for more complicated data structures
