

Increasing Dynamism in Plasticine

YaqiZhang yaqiz@stanford.edu Alexander Rucker acrucker@stanford.edu

Matthew Vilim mvilim@stanford.edu

— Background —

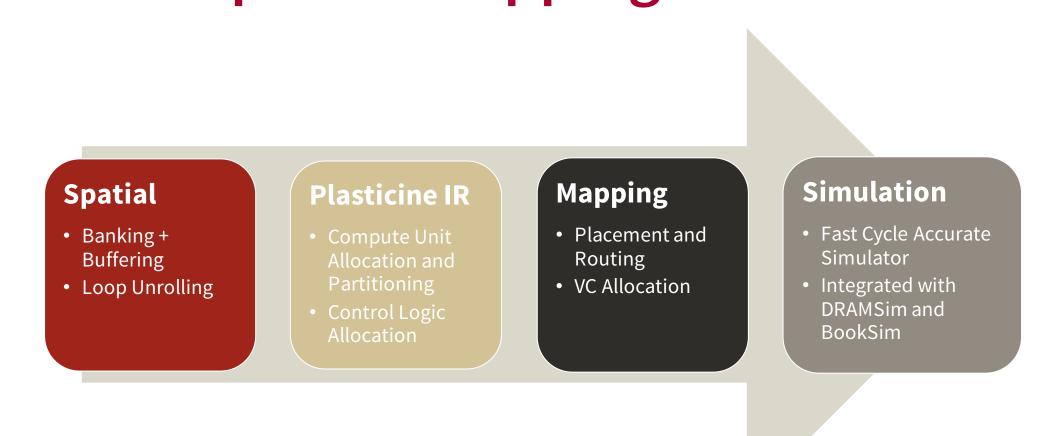

Plasticine is a vector Coarse-Grained Reconfigurable Array:

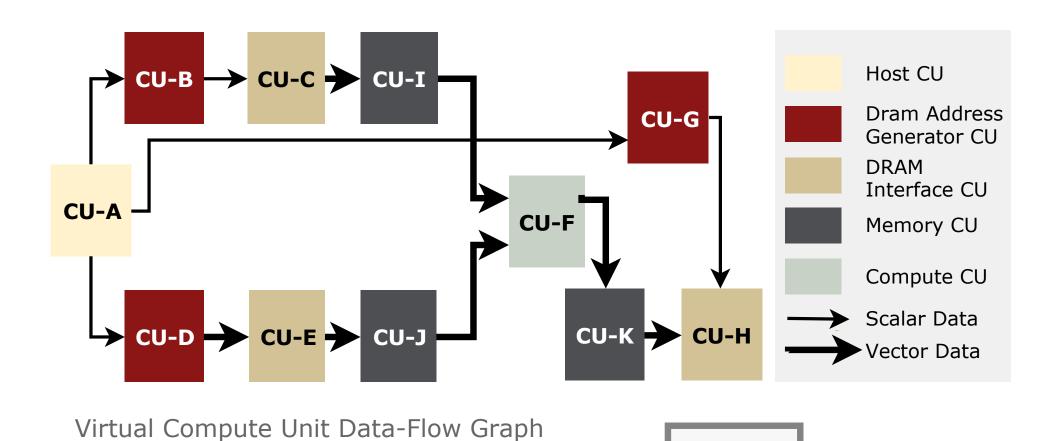

- 6-stage, 16-lane 32-bit floating point SIMD pipelines
- Distributed 256-kByte memories
- Memory controllers support dense and sparse DRAM access

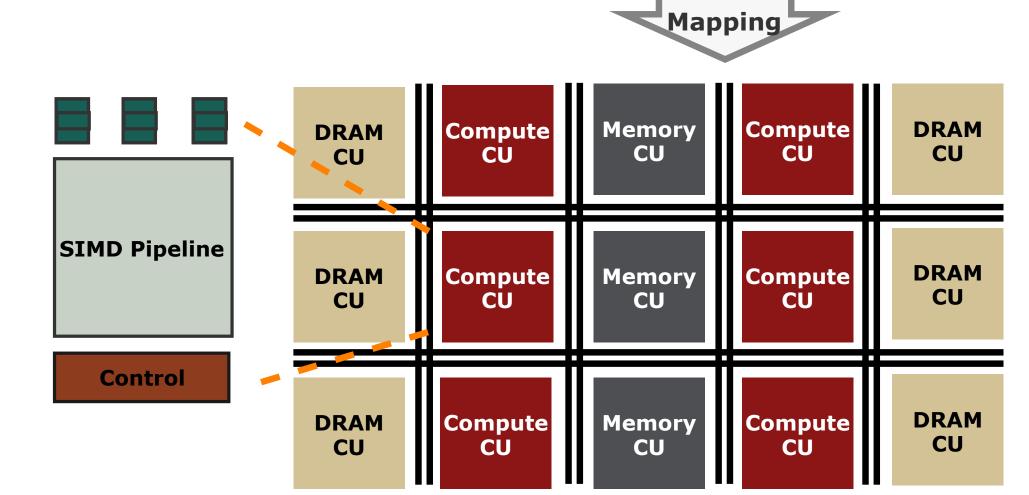

Plasticine demonstrated up to 95x speedup and 77x performance per watt vs. a Stratix V FPGA.

How can we retain Plasticine's performance and efficiency while enabling new applications?

— Compiler & Mapping Flow ———

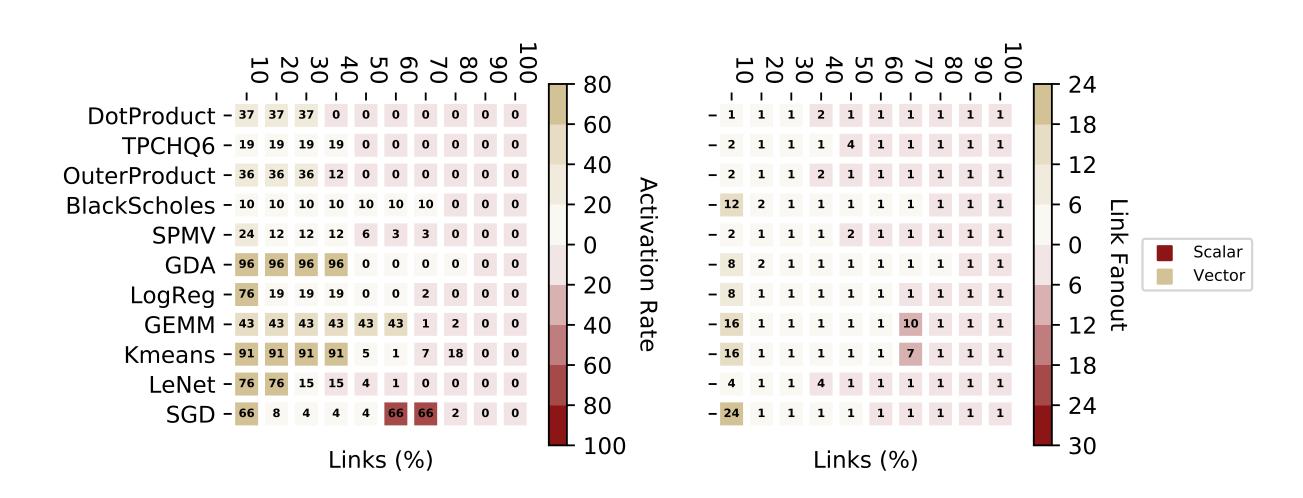

Physical Compute Unit

— Hybrid Networks –

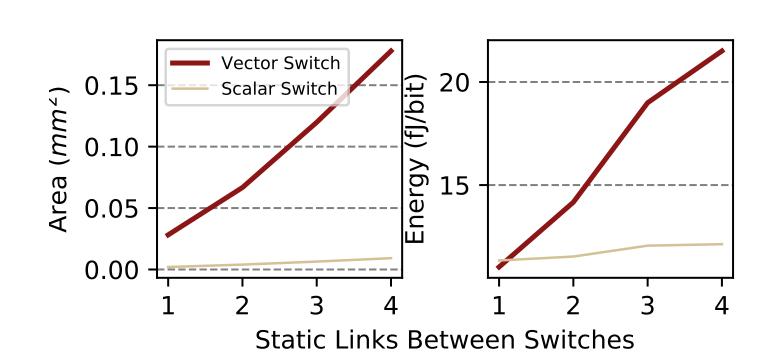

Different applications have different link activation rates and fanouts:

How can we improve link utilization?

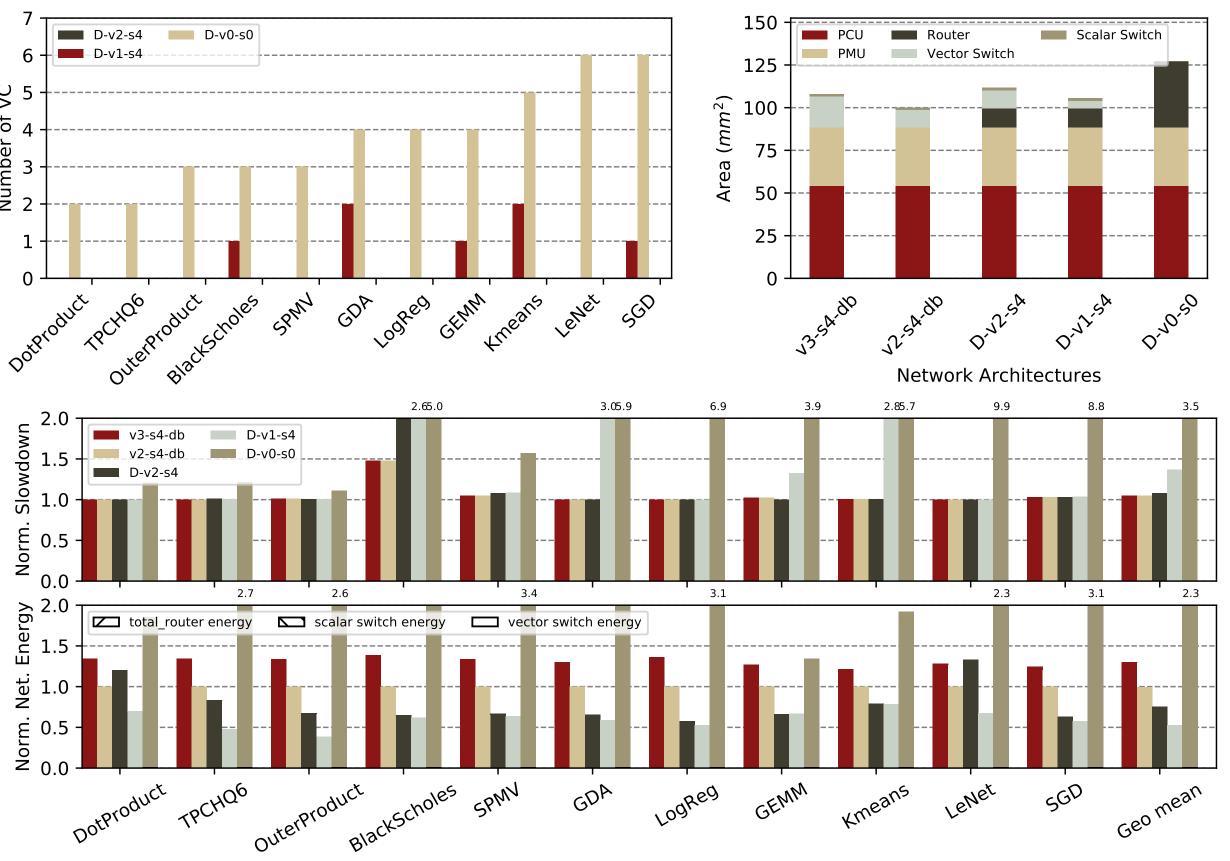

- Use static network for high-bandwidth and broadcast links
- Use dynamic network to encourage link sharing on low-activation links
- Specialize networks at different granularities

Area and energy scaling for switch and router on 28nm technology:

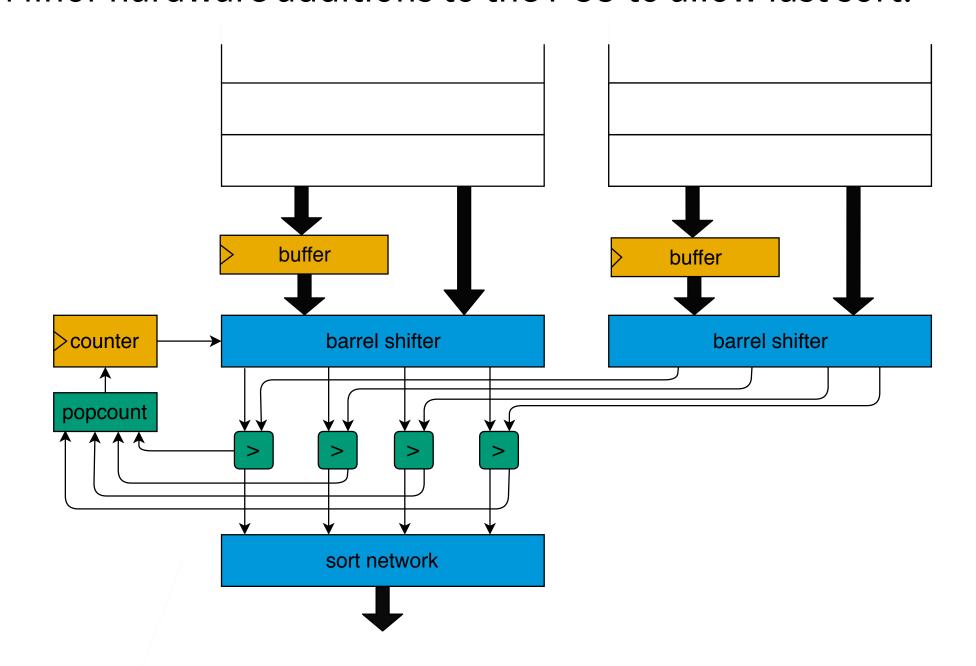

#VC B	uffer Slots	S Area (μm^2)	Energy(fJ /bit)
4	2	72426.39	31.19
2	4	70390.01	28.44
4	4	127695.32	36.11
8	4	241833.85	52.47

Network evaluation for different benchmarks:

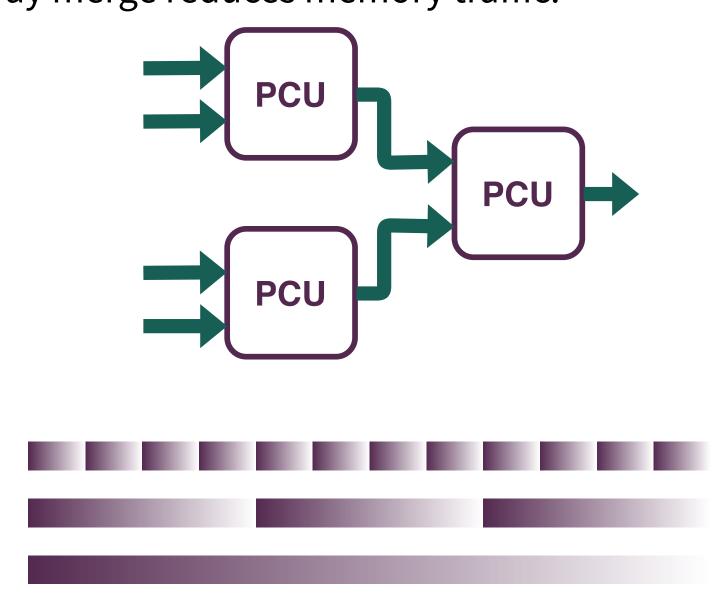

— Future Work ———

Minor hardware additions to the PCU to allow fast sort:

Multi-way merge reduces memory traffic:

What's the next class of applications to target?

- Transactional/online applications?
- Streaming data analytics and networking?
- Graph analytics?

What advances will be necessary to target these applications?

Improve achieved density for generic control constructs:

- Data-dependent conditionals
- Finite state machine-based control
- Parsing support
- Support for more complicated data structures
